Every number carries its proof.

A review workspace for supported decisions, not another spreadsheet.

Review in context

Six destinations organize the engagement. Selecting a number opens its source, exact field, supplied calculation and human review history in the X-ray Inspector. A professional can follow the evidence without losing their place; a new hire can distinguish a pipeline reading, an engine result and an accountable conclusion. Prior-year swings and independent reconciliations surface questions instead of treating confidence as truth.

The data model

Record	Responsibility
clients + engagements	Client/year/content-hash identity; immutable pipeline packet and transactional review projection.
workpaper_adjustments	Versioned line, source-field and asset overlays; original, reviewed value, author, reason and explicit tax effect.
review_records + audit_events	Verification, dispositions, questions, judgments, approvals, assignments and complete attributed history.
firm_policies + command_receipts	Shared firm standards; actor/payload-bound retries, revision conflicts and atomic commits.
attachments + handoff_archives	Private original bytes with integrity hashes; full prior reviews linked into next-year engagements.

How an edit becomes evidence

Every mutation validates the selected role and expected revision on the server. State, normalized records, audit and retry receipt commit together. Changes retain the original, reopen content-bound approvals and appear in each reviewer's unread-change view. Filing gates require supported conclusions and approvals; filing freezes a snapshot, and an amendment becomes a new cycle above it. Carryforward preserves the complete prior review while a genuine new-year packet supplies new-year calculations.

Deliberate tradeoffs

The assignment starts after extraction. Simulated printed sources keep stable references so original files can replace them. There is no OCR or tax-engine rerun: estimates use supplied rates, payments/credits use direct effects, and five supplied what-ifs remain isolated. Embedded Postgres enables local evaluation; Supabase supports shared persistence. Role switching, signatures and filing are demonstrations, not real identity or agency integrations. Public demo access must never be presented as protection for real taxpayer data. Codex assisted implementation and verification; runtime checks are deterministic.
